Vanessa A. Countryman
Secretary
Attention: File No. 4-927, Order Granting Temporary Conditional Exemptive Relief for Tokenized NMS Stock
U.S. Securities and Exchange Commission
100 F Street NE
Washington, DC 20549-1090

October 19, 2026

Re: File No. 4-927; Release No. 34-106402; Order Granting Temporary Conditional Exemptive Relief from the Definitions of "Exchange" and "Dealer" for Tokenized NMS Stock, and Request for Comment (issued September 17, 2026; 91 Fed. Reg. 60168, September 22, 2026)

Dear Ms. Countryman:

Tokenization Systems, an independent research program on stablecoin, tokenization, and digital-asset market structure, submits this comment on the Commission's order granting the TSV Exemption and the Covered Firm Exemption (the Order). Tokenization Systems supports the Commission's decision to let trading of Tokenized NMS Stock begin under stated conditions while it considers rulemaking, and supports in particular the condition that the smart contracts a Tokenized Securities Venue (TSV) uses be "auditable, public, and deployed on a public, permissionless distributed ledger." That condition is what makes the recommendations below inexpensive: most of the facts they ask for are already public on the ledger the Order requires.

The Order is designed to produce evidence. The Commission "anticipates that experience with the Order, both in the form of public input and the practical application of the exemptions, which are time-limited and subject to enumerated conditions, will help inform any future Commission actions in this area, including rulemaking" (91 Fed. Reg. at 60169), and expects that trading on TSVs "will help the Commission evaluate the impact of trading Tokenized NMS Stock using AMM Liquidity Pools and the TSV trading model on the national market system" (id. at 60172). Commissioner Peirce's statement on the Order puts the purpose plainly: exemptions like this one "are intended to provide the Commission and market participants with an opportunity to observe how tokenized NMS stocks are used and traded in different onchain contexts and how onchain and traditional markets interact with one another." This comment's central proposition is that several of the Order's conditions turn on facts the ledger already makes observable, but the Order collects those facts as descriptions of procedure, collects some of them only for the TSV's own smart contracts rather than for the assets traded in its pools, and does not collect others at all. A five-year exemption whose purpose is to inform rulemaking should collect, from its first day, the facts that rulemaking will need, in a form a reviewer can check against the ledger rather than accept on representation.

Three examples show the gap. First, the Order requires a TSV to name who can upgrade, modify, suspend, override, or cease its own smart contracts, but asks no equivalent question about the token contracts of the Tokenized NMS Stock, stablecoin, or tokenized money market fund in each pool, although those contracts commonly carry functions to mint, freeze, force a transfer, pause, or replace their own code. Second, the Order deems a token to carry the same rights as the share by reference to four rights a shareholder holds against the issuer, while the Commission's own staff has identified an exposure that third-party tokenization adds and that none of the four reaches: the holder's exposure to the third party itself, "such as bankruptcy." Third, the Order requires transaction prices in U.S. dollars but not the rate used to convert a stablecoin price into dollars, so a reader of the data cannot tell a move in the stock from a move in the stablecoin it traded against.

Tokenization Systems' measurement work bears on each. Its Minimum Viable Equivalence Pack (MVEP), published on SSRN, is a ten-category structural-equivalence diagnostic for tokenized products; applied to fourteen named tokenized money and collateral products, it rated every one of them non-equivalent at the headline. Its on-chain measurements of tokenized Treasury funds and stablecoins, and its fifty-two-protocol governance audit published in *Frontiers in Blockchain* in August 2026, are described where they bear. Where a finding comes from products other than Tokenized NMS Stock, which is not yet traded under the Order, this comment says so at the point of use and offers it for what it shows about the control layer of tokenized assets generally.

Tokenization Systems' first comment to the Commission, on the Draft Strategic Plan for Fiscal Years 2026 through 2030 (File Number DSP-3), recommended reproducible on-chain measurement of control. Recommendation 2 below applies that recommendation here, through an inventory of privileged functions. This comment addresses Questions 1, 3, 4, 5, 8, and 10, and the operational part of Question 7. It takes no position on the duration or permanence of either exemption (Questions 2 and 9), on the calibration of the Tier 1 and Tier 2 limits (Question 6), on relief from Regulation NMS for broker-dealer participants (the second part of Question 7), or on whether TSVs should trade securities other than NMS stock (the first part of Question 4), because it has no evidence to offer on them. For the same reason it takes no position on the issuer notice and objection mechanics of Sections II.C and II.D, including Computershare's request of October 2, 2026 that the Commission "provide prompt guidance that an issuer may establish a standing objection" and publish registers of TSVs and of issuer objections. None of the recommendations requires the use of any program instrument: the MVEP and the program's on-chain measurements are cited for the facts they show a review must establish, and any reviewer may establish those facts by its own method.

The seven recommendations are summarized below with the questions each answers and the action requested.

Recommendation	Questions	Requested action	Why it matters
1. Verify equivalence through the custody chain and the holder's position if the tokenizer fails, and state the evidence	1, 3, 5	Require the Section II.E verification and Notice item (i) to cover the tokenization model, the controlling record and its reconciliation, the holder's position if an intermediary fails, corporate actions, and conversion between token and share	A token can carry the four rights the Order names while the holder's claim runs against a custodian
2. Extend the change-control disclosure to every asset traded on the TSV	1, 4, 5	Add a Notice item listing each asset's privileged functions, who holds them, and whether approval by more than one person and a delay apply; treat an exercise that freezes, burns, moves, or pauses a pooled asset, or by the TSV or a Covered Firm, as a significant operational event	Item (n) reaches only the TSV's own contracts
3. State when each leg of a trade is final and who bears loss if it is reversed or frozen	4, 5, 7	Require Notice item (y) to give, for each asset, the ledger event treated as final, its legal effect, and the loss allocation	Settlement is "near instantaneous" only if the ledger event is the legal transfer for both assets
4. Add the ledger transaction identifier and the dollar conversion rate to each transaction record	3, 5	Add both to the Section II.G minimum fields	Without them, a stablecoin deviation reads as a dislocation in the stock, and no print can be reconciled to the ledger
5. Ask Covered Firms for their control over pool parameters and their share of pool liquidity	8, 10	Add both to the Covered Firm notification and records	Control over pricing is the indicium of dealing the Order names, and it is observable
6. Determine affiliation for the volume and symbol limits by who holds a pool's privileged functions	5	Treat TSVs as affiliated where the same persons can exercise those functions over a pool each provides	Common control can sit with a shared key holder

Recommendation	Questions	Requested action	Why it matters
7. Address the GENIUS Act's July 18, 2028 offer-and-sale restriction before it applies	4	With Treasury, state how section 3(b)(1) applies to a TSV's pairing of a payment stablecoin, and require the Notice to state each paired stablecoin's issuer status	The date falls inside the Order's term, and footnote 24 leaves the question open

I. Recommendations

Recommendation 1 (Questions 1, 3, and 5; Section II.E and Notice items (h), (i), and (cc)): Verify equivalence through the custody chain and the holder's position if the tokenizer fails, and state the evidence relied on.

Section II.E requires a TSV to "verify that the Tokenized NMS Stock made available for trading on the TSV provides holders the same rights and privileges as does traditional NMS stock of an equivalent class," and deems that standard met if, "among other things," the token conveys the same interest in the company, the same dividends, the same voting rights, and the same share of residual assets on liquidation (91 Fed. Reg. at 60174). Notice item (i) asks the TSV to describe "the steps (e.g., audits, certifications, attestations)" it has taken to verify this (id. at 60178).

The four rights the Order names are the rights of a shareholder against the issuer, and the Commission has itself recognized that tokenization can change them. Its 2026 interpretation of how the federal securities laws apply to crypto assets, which the Order cites, states: "There are a variety of models used to tokenize securities, but they may vary in terms of structure and the rights afforded to holders. As such, the rights of a holder of the crypto asset may be materially different from the rights of a holder of the underlying security, including economic and voting rights." For Tokenized NMS Stock tokenized by an unaffiliated third party, the Commission's staff has identified a further exposure that sits outside all four rights. Its January 2026 Statement on Tokenized Securities, on which the Order draws for its definition of Tokenized NMS Stock, observes that the crypto asset "may or may not confer upon the holder of the crypto asset any rights as a holder of the underlying security," and that "holders of the crypto asset may be exposed to risks with respect to the third party, such as bankruptcy, to which a holder of the underlying security would not necessarily be exposed." Commissioner Peirce made the same point in July 2025: "Purchasers of these third-party tokens may face unique risks, such as counterparty risks," and a token "could be a 'receipt for a security,' which is itself a security but is distinct from the underlying security held by the distributor of the token."

A token can therefore satisfy every right the Order names while the holder's claim runs against a custodian rather than the issuer, while the record that controls ownership sits off the ledger, and while the token's supply is not reconciled to the shares held for holders. Each is a way in which the holder of the token is not in the position of the holder of the share, and none is visible in an attestation that the four rights are present.

The MVEP was built to test this question for tokenized products, and five of its ten categories bear on it directly: rights parity, the system of record, records and reconciliation, custody and customer property, and insolvency posture. Applied to a sample of named tokenized money and collateral products, it found that no major U.S. tokenized financial product passes its rights-parity and settlement-finality categories cleanly, and that products treated as equivalent in market use separate once the holder-rights and settlement evidence beneath the label is tested. The MVEP's subject is tokenized money and collateral products rather than equities, so it is offered here as method: it identifies which facts an equivalence verification has to establish, whatever the underlying asset.

Tokenization Systems recommends that the Commission state that the Section II.E verification, and the Notice item (i) description of it, must address five things: (1) the tokenization model, in the terms of the staff statement (issuer-sponsored, with the ledger forming part of the master securityholder file or used to notify an off-chain record; or third-party custodial, as a tokenized security entitlement); (2) which record controls if the ledger and the off-chain record disagree, and how often the token supply is reconciled to the shares held for holders; (3) the holder's position if the tokenizer, custodian, or any other intermediary in the chain fails; (4) how stock splits, mergers, tender offers, and other corporate actions are applied to the token, and by whom; and (5) who may convert the token into the underlying share and back, and on what terms.

The fourth item is where a token most often parts from the share in practice. Tokenization Systems' analysis of tokenized equity rails found that around-the-clock trading creates a structural mismatch with business-day record updates at the depository, so that stock splits, ex-dates, and dividend record dates can produce divergent on-chain and depository records across weekend trading, and it identified three ways to resolve the mismatch: halting trading during corporate-action processing windows, treating the ledger as the authoritative record, or synchronizing two records. That analysis concerns exchange-listed tokenized shares and is forward-looking (when it was written, no tokenized equity had processed a stock split on a 24/7 trading rail), but the mismatch arises for any token whose underlying share is recorded off the ledger. The Order already asks, in Notice item (cc), for "any procedures to address price volatility or trading involving, for example, corporate actions occurring when markets for the underlying securities are closed" (91 Fed. Reg. at 60180). The TSV's answer should name which of the three approaches it uses, the moment at which an ex-date adjustment takes effect on the token, and how a dispute about it is resolved; this is also the part of Question 3, on overnight trading, on which Tokenization Systems has evidence to offer. Traditional venues are doing the same for extended-hours trading: at the Commission's roundtable on 24-hour trading, held the day the Order issued, Commissioner Peirce noted that "trading venues have established standards to determine how to treat certain corporate actions in this new environment."

The fifth item governs price as well as rights. A token's price stays aligned with the share's only through participants able to convert one into the other, and the evidence from stablecoins is that the width of that channel matters, in both directions. Yiming Ma, Yao Zeng, and Anthony Lee Zhang write that "issuers could simply authorize more arbitrageurs and make arbitrage more efficient to improve price stability in secondary markets," and

also that, "while limiting arbitrage is harmful to stablecoin price stability," limiting it "can, in fact, reduce the likelihood of panic runs" (NBER Working Paper No. 33882, 2025). The program's comment to the OCC (Docket OCC-2025-0372) reported the finding of Christopher Odinet, Andrea Tosato, and Yesha Yadav that only 882 verified Tether accounts and 1,834 Circle accounts have direct redemption rights, with the remaining holders exiting through secondary-market intermediaries (Yale Law Journal, forthcoming). Who may tokenize and detokenize a Tokenized NMS Stock is the same channel. The paper concerns stablecoins and is offered for the channel, not as a reason to widen it; the Notice should name who may use it.

These are facts a TSV must establish in order to verify equivalence at all. The recommendation asks that they be stated rather than summarized as an attestation, and it answers a question Commissioner Peirce put to the Investor Advisory Committee before the Order issued: "Should the Commission consider allowing different tokenization models in an innovation exemption to help inform their risks, benefits, and regulatory treatment?" A model the Notice does not name cannot inform anything.

Recommendation 2 (Questions 1, 4, and 5; Section II.A and Notice items (h), (n), and (dd)): Extend the change-control disclosure from the TSV's own smart contracts to every asset traded in its pools.

Notice item (n) requires a TSV to describe "any circumstances under which the distributed ledger applications used by the TSV can be upgraded, modified, suspended, overridden, or ceased," the persons who can do so, "whether unilaterally or in combination," and the names or roles of those persons (91 Fed. Reg. at 60179). That is the right question. The Order asks it about the TSV's own applications. It does not ask it about the token contracts of the Tokenized NMS Stock, the stablecoin, or the tokenized money market fund held in each pool, although those contracts commonly carry functions that can mint or burn units, freeze or block an address, force a transfer, pause all transfers, restrict transfers to an allow-list, or replace the contract's code. Any of those functions, exercised on an asset held in an AMM Liquidity Pool, changes what TSV Participants hold and what the pool's price means. Item (h) comes closest, asking the TSV to describe the procedures it uses to evaluate "the legal status, technical soundness, and operational integrity" of each Tokenized NMS Stock and its distributed ledger system (id. at 60178), and item (dd) asks about "processes to burn or detokenize" a token (id. at 60180). A description of procedures is not an inventory of functions, and neither item reaches the paired asset. The Commission made the relevant judgment one month before the Order. Proposing Regulation Crypto Assets, it explained that disclosure of an asset's governance mechanisms and permissions "would help investors understand the conditions under which changes may be made to the subject crypto asset or the associated crypto network or associated crypto application and who may be empowered to make such changes" (91 Fed. Reg. 54510, 54527 (Aug. 21, 2026)). A TSV Participant holding a token in a pool needs the same understanding of that token.

The program's on-chain work shows that these functions are not theoretical, and that the controls around them are often thin. In its verification of the four major tokenized

Treasury products, as documented in March 2026, no administrative control chain carried a timelock; in some cases a single proxy owner address, backed by off-chain key management rather than an on-chain multisignature wallet, can replace the token's implementation contract in a single transaction; and in others one shared multisignature wallet controls several products, so that a single compromise could affect the whole product family. One of the four is the token of a registered money market fund, and tokenized money market fund shares are among the assets the Order permits a TSV to pair with Tokenized NMS Stock.

A later measurement of one of the largest of these funds, taken on October 1, 2026, enumerated the role grants of its token contract from the ledger alone: thirteen role holders on Ethereum, four of them externally owned accounts, among them an owner holding the upgrade power on all six chains measured and a transfer-agent role that can burn, seize, and pause. That measurement reads on-chain authority only, and an off-chain control may stand behind any key; what it shows is that the inventory recommended below can be produced from public data, without the issuer's cooperation.

A paired payment stablecoin carries the same class of function. On October 15, 2025, a minting address belonging to a highly regulated payment stablecoin issuer created 300 trillion units of its stablecoin, roughly five orders of magnitude above the token's circulating supply, and burned the position 22 minutes later. The peg held, and the episode caused no market harm; its relevance is that one transaction from one address created units far exceeding the asset's supply, an event an AMM Liquidity Pool pairing that asset with Tokenized NMS Stock would price mechanically. That issuer scored 0.90 on the freeze and mint capability dimension of Tokenization Systems' Control Layer Intensity Index, the top of the band for a verified freeze function with a documented response time, while a supply cap, a per-transaction limit, and multisignature minting were all absent. That is a limitation of the program's own instrument, and Tokenization Systems states it as one: the index scores whether a capability exists, not the quality of the controls around it. An inventory that names who holds each function, and whether approval by more than one person and a delay are required, reaches the controls as well as the capability.

Commissioner Peirce's statement on the Order explains why the identity of these key holders matters. "This order is not about decentralized finance," she writes, because "[t]ruly decentralized systems that are driven by automated software do not give rise to the foundational concerns underlying securities regulation, namely that an intermediary you trust to act on your behalf will be foolish, careless, or compromised." A pool whose assets can be minted, frozen, seized, paused, or rewritten by an identifiable key holder is not such a system: the key holder is an intermediary of exactly that kind, and the inventory tells TSV Participants who it is. The International Monetary Fund's 2026 note on tokenized finance reaches the same point from the supervisory side: "the governance challenges concern not only code quality but also the processes that design, validate, modify, and, if necessary, override code." The underlying design principle is an old one. Jerome Saltzer and Michael Schroeder's statement of separation of privilege holds that "a protection mechanism that requires two keys to unlock it is more robust and flexible than one that allows access to the presenter of only a single key," because then "no single accident, deception, or breach of trust is sufficient to compromise the protected information."

Whether an asset's privileged functions require more than one key is one of the facts the recommended inventory would show.

Tokenization Systems recommends a Notice item that lists, for each Tokenized NMS Stock and each paired asset made available on the TSV, each function by which any person can mint, burn, freeze, block, force the transfer of, pause, restrict the transfer of, or upgrade or replace the code governing the asset; the address at which each function resides; the person or persons who can exercise it; and whether its exercise requires approval by more than one person or is subject to a delay. The TSV should revise the Notice within five business days of any change. An exercise of any such function should be treated as a significant operational event under Section II.I, which already reaches "an event that has a significant impact on the operation of the TSV or on its participants" (id. at 60176), when it freezes, blocks, burns, or forces the transfer of units held by an AMM Liquidity Pool the TSV provides, or pauses transfers of an asset in that pool, or when the TSV or a Covered Firm supplying that pool holds the function; any other exercise, such as a third-party issuer's mint or code upgrade, is a significant operational event only if it meets that test. The Commission's staff has drawn this line before: its December 2025 no-action letter for the Depository Trust Company's tokenization service rested, among other representations, on DTC's undertaking to give Division staff a quarterly report that includes "[a]ny instances in which DTC used its 'root wallet' to address Conditions Requiring Reversal during the quarter." Recommendation 2 asks for the TSV equivalent, reported as it happens rather than quarterly. The Commission should also confirm that "auditable" in Section II.A includes the authority to replace the audited code: an audit of a contract's code is only as durable as the control over replacing that code. Gabriel Shapiro's comment of September 19, 2026 would go further and make the exemption unavailable where any person holds a power to mint, burn, freeze, force the transfer of, or sever the token from the securities that "has not been published together with who holds it and on what conditions"; Recommendation 2 asks the Commission to collect that inventory while the exemption runs, not to withdraw the exemption where such a power exists.

Recommendation 3 (Questions 4, 5, and 7; Notice item (y)): State, for each leg of a trade, when the transfer is final and who bears the loss if it is reversed or frozen.

The Order lists "near instantaneous settlement" among the benefits TSVs may offer (91 Fed. Reg. at 60171), and Notice item (y) asks a TSV to "Describe any procedures or material arrangements undertaken to facilitate clearance and settlement of transactions on the TSV" (id. at 60179). A TSV trade settles two assets, and each leg's finality depends on the rules governing that asset. The staff statement's analysis of tokenized securities rests on an assumption that does this work: that "a transfer of the crypto asset results in a transfer of control of the security or security entitlement and/or ownership of the security or security entitlement via an effective indorsement, instruction, or entitlement order, as the case may be." Where an off-chain record controls ownership, the on-chain transfer is an instruction to update that record, and the trade is final for the holder when the record is updated, not when the block is confirmed. Even the most conservative tokenization designs reserve a

power to reverse: the Depository Trust Company states that it "retains full administrative control over its tokens, including claw-back and force transfer capabilities, if tokens are lost or stolen." A transfer that an administrator can reverse is final only in the sense the administrator's rules define, which is why those rules should be stated for each leg.

The MVEP's settlement-finality category asks three questions of a tokenized product: the on-chain event at which a transfer becomes legally irreversible, mapped to a legal status under the operator's rules; the corresponding point of irreversibility for transfers routed through intermediaries, with the allocation of risk if an intermediary fails; and when the transfer discharges the underlying obligation. A response that relies on block confirmation alone, without a legal mapping, does not satisfy it. Applied to named products, every fiat-backed stablecoin in the MVEP's sample failed this category, because none publishes a finality analysis comparable to UCC Article 4A, while the tokenized money market funds partially passed it, because securities settlement has an established finality framework through DTC and NSCC with which the on-chain layer can be aligned. A stablecoin is the paired asset the Order offers as its example, and a TSV trade settled on the ledger does not pass through that framework, so each leg needs its own statement of finality. The MVEP's exception-handling category adds the reorganization case: detection, halt criteria, and loss allocation if the ledger reverses a transfer that the off-chain record still shows as complete.

The same question arises across venues. Tokenization Systems' stress analysis of tokenized equity rails found that where one venue settles instantly and another at T+1, the timing mismatch creates free optionality for arbitrageurs and counterparty risk for market makers, and it concluded that a cross-venue definition of settlement finality is needed. That scenario is hypothetical, but it is the position of a broker-dealer TSV Participant that hedges a TSV trade in the underlying NMS stock, which bears on the operational challenges Question 7 asks about.

The post-trade freeze case is concrete for the paired asset. Circle's published Stablecoin Access Denial Policy states that when an address is denied access, "all of the Circle Stablecoin controlled by that address is blocked and cannot be transferred on-chain," and that "[i]t is not possible to deny access to individual Circle Stablecoin tokens." An AMM Liquidity Pool holds the stablecoin of every liquidity provider at one contract address, so a block on that address would freeze the stablecoin side of the whole pool, and the Notice should say who bears that loss.

Tokenization Systems recommends that Notice item (y) state, for each asset in a trading pair, the ledger event at which the TSV treats the transfer as final; the legal effect of that event under the terms governing the asset, including whether it transfers the security or security entitlement or instructs an off-chain record; and how loss is allocated if a completed transfer is reversed by a reorganization of the ledger or the asset is frozen after execution. These are facts the TSV must know to describe its clearance and settlement arrangements accurately; the recommendation asks that the description be specific enough to be checked.

Recommendation 4 (Questions 3 and 5; Section II.G): Add the ledger transaction identifier and the U.S. dollar conversion rate to each transaction record.

Section II.G requires each TSV to publish U.S. dollar-denominated transaction data within ten minutes, including the symbols, price, size, "the transaction time at the AMM Liquidity Pool," and direction of each transaction (91 Fed. Reg. at 60176). Footnote 78 requires conversion "using consistent, impartial, and reasonable methods commonly applied by market participants for converting the value of an asset that is not quoted in U.S. dollars" (id.). Two additional fields would let this data serve the evaluation the Order describes.

The first is the conversion rate. An AMM Liquidity Pool prices Tokenized NMS Stock in the paired asset. When the paired asset is a stablecoin, the dollar price a TSV reports is the pool price multiplied by the rate at which the TSV converted the stablecoin to dollars. The Order requires the method to be consistent and reasonable but does not require the rate to be reported, so a reader cannot tell whether a reported price moved because the stock moved or because the stablecoin did. The distinction matters in practice. Yiming Ma, Yao Zeng, and Anthony Lee Zhang document that "stablecoin trading prices in secondary markets frequently deviate from $1" (NBER Working Paper No. 33882, 2025), and in the March 2023 banking stress the stablecoin of the operator scoring highest on Tokenization Systems' Control Layer Intensity Index fell 10.4 percent below par on an hourly decentralized-exchange volume-weighted basis, and 13 percent at the centralized-exchange intraday low, while a lower-scoring operator's stablecoin held its peg. Those two figures describe the same event and differ only in venue and frequency, which is to say in the choice of conversion source, and that choice alone moves the measured price by more than two and a half percentage points. The episode also unfolded over a weekend, while redemption at the issuer, available only in banking hours, was gated and secondary trading continued, which is the pattern a TSV trading around the clock will meet. A TSV that converted at par through such an episode would report dollar prices for a Tokenized NMS Stock that diverge from the underlying NMS stock by the size of the depeg, and a reviewer would read a stablecoin event as a dislocation in the stock.

The second is the transaction's identifier on the ledger. Every TSV trade is recorded on a public, permissionless ledger, and the identifier lets anyone reconcile a reported print to that record and lets the Commission recompute a TSV's reported figures. Stan E. Malone, founder of MONARK, made the same suggestion in his comment of September 24, 2026, that each transaction a TSV publishes under Section II.G identify "its on-chain transaction, so that a third party could recompute its price, size, time and direction from the public, permissionless ledger." Tokenization Systems' governance audit of fifty-two protocols shows why recomputation matters: concentration figures in prior holder-list studies were inflated by a median factor of 2.3 because they counted as independent holders addresses the protocols themselves controlled. That audit concerns governance tokens, not Tokenized NMS Stock; it is offered as method, to show that a figure computed from the same ledger can move by a large factor on a choice the reader cannot see.

The peer-reviewed evidence on AMM pricing indicates where such a comparison is likely to

find dislocation, if it finds any. Studying Uniswap pools against a centralized exchange, Alfred Lehar and Christine Parlour report that "[p]ricing differences between Uniswap and Binance are small except in the startup-phase of the Uniswap pool when liquidity is scarce" (Journal of Finance, 2025). Those were crypto-asset pools, not Tokenized NMS Stock, but the mechanism, a price set by the ratio of pool assets and corrected by outside arbitrage, is the one the Order describes, and it implies that dislocation will concentrate in new and thin pools. The Order's existing end-of-day pool-size field, with the two fields recommended here, would let the Commission test that implication directly, and would let it measure for TSV trading the concern Commissioner Peirce reported at the Commission's roundtable on 24-hour trading: "Some worry about the thinner order books overnight, wider spreads, and the resulting increased price volatility."

Tokenization Systems recommends adding to the Section II.G minimum fields (vi) the identifier of the transaction on the distributed ledger and (vii) for any pair whose other asset is not denominated in U.S. dollars, the conversion rate used to state the price in U.S. dollars and the source of that rate. Both are values the TSV already holds when it computes the dollar price. With them, the published data can be reconciled to the ledger and compared, print by print, with the consolidated quotation for the underlying NMS stock at the same moment, which is the measurement Question 3 asks about. Tokenization Systems has no evidence of its own on what that comparison will show for Tokenized NMS Stock, including around the opening, reopening, and closing processes; the recommendation is that the data be collected in a form that lets the Commission find out. Douro Labs' comment of October 9, 2026 asks the staff to confirm that a TSV may satisfy the footnote 78 standard by applying the principles Douro proposes for reference prices and "identifying the source in its notice under item (s)"; field (vii) supports that and adds what a source named once in the Notice cannot show, the rate applied to each print.

Recommendation 5 (Questions 8 and 10; Section IV.A): Ask Covered Firms for their control over the parameters of pools they supply and their share of each pool's liquidity.

The Order identifies, as the conduct that may make liquidity provision dealing, a provider that would "assert control over pricing and inventory of committed liquidity to AMM Liquidity Pools pursuant to agreements, arrangements, or other understandings" (91 Fed. Reg. at 60182), and grants the Covered Firm Exemption "while the Commission evaluates the scope of the term 'dealer' more broadly" (id.). On a ledger, control over a pool's pricing is exercised through identifiable acts, and the Order lists them itself when it explains what it means for a TSV to provide a pool: "deploying an AMM smart contract for trading a given pair of assets, setting or altering the rules or parameters of the pool, determining the fees for the pool, and/or having the ability to pause trading in the pool" (id. at 60170). It also asks each TSV to describe "any governance rights of LP tokens" (id. at 60178).

The economics of AMM liquidity provision draw the same line the Order draws. Lehar and Parlour show that "[l]iquidity suppliers in the AMM rely on outside arbitrageurs to set the correct price at which the liquidity is provided": a supplier of that kind trades against the pool's price and does not set it, which is the trader activity the Order describes. A supplier

that also holds a pool's parameter, fee, or pause controls is in a different position. The Covered Firm notification asks for the firm's business model, its liquidity agreements, and its incentives, but not whether the firm holds any of those roles or rights over a pool it supplies, or how much of the pool's liquidity it supplies. Those two facts are the observable form of the control the Order identifies, and the second matters for pricing as well as for dealer status: a Federal Reserve Board staff working paper on the Terra collapse traces the depeg of a stablecoin in a Curve liquidity pool to a large liquidity withdrawal that left the pool shallower, followed within the hour by two traders swapping 185 million UST for USDC (Badev and Watsky, FEDS 2023-044).

A liquidity share alone can mismeasure control where pool tokens carry governance rights that can be delegated: in Tokenization Systems' audit, where governance ran through delegation, voting power was more concentrated than token holdings in thirteen of eighteen protocols with sufficient governance data, with a median amplification of 4.4 times, alongside five design-driven exceptions in which delegation dispersed voting below holdings. Those are governance tokens of decentralized-finance protocols, offered to show that holdings and control can diverge in either direction, which is why both facts are needed.

Tokenization Systems recommends adding to the Covered Firm notification, and to the records a Covered Firm must keep, any key, role, or governance right held by the Covered Firm or its affiliates that can set or alter the parameters, fees, code, or pause state of an AMM Liquidity Pool to which it supplies liquidity, together with its share of each such pool's liquidity at the end of each calendar month. This gives the Commission, for the broader evaluation of the dealer definition that the Order anticipates, the facts that distinguish a liquidity provider that trades against a pool from one that controls how the pool prices. As Commissioner Peirce wrote of the Order, "Before jumping to regulatory conclusions, we want to see who uses the exemptions and how."

Recommendation 6 (Question 5; Section II.F): Determine affiliation for the volume and symbol limits by who can exercise a pool's privileged functions.

The volume and symbol limits aggregate a TSV's trading with that of its affiliated TSVs, a requirement "intended to help avoid a situation in which businesses are structured into multiple TSVs to avoid triggering the volume and symbol limitations" (91 Fed. Reg. at 60174-75). Affiliation turns on control, which the Order defines as "the power, directly or indirectly, to direct the management or policies of a TSV, whether through ownership of securities, by contract, or otherwise" (id. at 60172 n.45). On a ledger, the decisive power over a pool is held by whoever holds its privileged functions, and that can sit with a shared key holder across entities that are not affiliated in the corporate sense. The program's finding that one shared multisignature wallet controls several tokenized Treasury products is an instance of exactly this.

Tokenization Systems recommends that the Commission confirm that control "by contract, or otherwise" includes the ability to exercise the privileged functions described in Recommendation 2, so that, for the aggregation conditions, TSVs are affiliated where the same person, or persons acting together, can exercise those functions over an AMM

Liquidity Pool that each provides. This adds no new category of affiliation and no disclosure beyond Recommendation 2, and it does not reach a shared software vendor, data provider, or node operator that holds no such function. It applies the Order's own control test to the form control takes on a ledger, and it is consistent with the effective-control positions Tokenization Systems has taken before the Financial Crimes Enforcement Network and the Federal Deposit Insurance Corporation.

Recommendation 7 (Question 4; footnote 24): Address the GENIUS Act's July 18, 2028 offer-and-sale restriction before it applies to a TSV's pairing of a payment stablecoin.

The Order "does not limit the type of non-security crypto asset a TSV can pair with a Tokenized NMS Stock" (91 Fed. Reg. at 60170), and it "does not provide any interpretation as to whether TSVs are, or could be, 'digital asset service providers,' as the term is defined in the GENIUS Act" (id.). That question has a date attached. Section 3(b)(1) of the GENIUS Act provides, subject to exceptions in subsection (c) and section 18, that "beginning on the date that is 3 years after the date of enactment of this Act, it shall be unlawful for a digital asset service provider to offer or sell a payment stablecoin to a person in the United States, unless the payment stablecoin is issued by a permitted payment stablecoin issuer" (Pub. L. No. 119-27, § 3(b)(1), 139 Stat. 419, 423 (2025)). The Act defines "offer" to mean "to make available for purchase, sale, or exchange" (§ 2(21)), and defines a digital asset service provider to include, subject to exclusions, a person that for compensation or profit engages in the business in the United States of "exchanging digital assets for other digital assets" (§ 2(7)(A)(ii)). The Act was enacted on July 18, 2025, so the prohibition applies from July 18, 2028, the date the Department of the Treasury's pending implementing proposal states (91 Fed. Reg. 53368, 53368 (Aug. 18, 2026)). That date falls inside the Order's term, which runs to September 17, 2031, and an AMM Liquidity Pool that pairs a payment stablecoin with Tokenized NMS Stock makes the stablecoin available for exchange.

Tokenization Systems does not recommend, on the evidence it has, that the Commission limit the paired asset by type; Recommendations 2 and 3 instead condition the pairing on the paired asset's observable control and finality facts, which apply to a stablecoin and a tokenized money market fund alike. It does recommend that the Commission, with Treasury, state before July 18, 2028 how section 3(b)(1) applies to a TSV's pairing of a payment stablecoin, and that in the meantime the Notice identify, for each paired payment stablecoin, whether its issuer is a permitted payment stablecoin issuer. If a TSV is a digital asset service provider, a pair it lists in good-faith reliance on the Order could otherwise become unlawful partway through the Order's term under a statute the Order expressly declined to interpret. In April 2026, Tokenization Systems told the Office of the Comptroller of the Currency that "[e]ach regulator supervises the instruments within its perimeter. Nobody supervises the seam where they are combined." A TSV trading pair is such a seam.

II. Suggested text for a modified Order

The Commission may modify any aspect of the exemptions under section 36 of the Exchange Act (91 Fed. Reg. at 60183). The following language is offered as a drafting starting point for the five highest-priority recommendations, using the Order's own defined terms.

Recommendation 1 (Section II.E, new final sentence).

> The TSV's verification must address, and its Notice must describe under item (i): the model by which the Tokenized NMS Stock is tokenized; which record of ownership controls if the distributed ledger and any other record disagree, and the frequency with which the supply of the Tokenized NMS Stock is reconciled to the securities held for holders; the position of a holder if the person that tokenized the security, or any custodian or other intermediary, becomes insolvent or otherwise fails; the manner in which corporate actions are applied to the Tokenized NMS Stock, and by whom; and the persons that may convert the Tokenized NMS Stock into the underlying security and back, and the terms on which they may do so.

Recommendation 2 (new Notice item (ee), Asset Control Functions).

> ee. Asset Control Functions: For each Tokenized NMS Stock, non-security crypto asset, and tokenized money market fund that the TSV makes available for trading, identify each function by which any person can mint, burn, freeze, block, force the transfer of, pause, restrict the transfer of, or upgrade or replace the code governing the asset; the address at which each function resides; the person or persons that can exercise it; and whether its exercise requires the approval of more than one person or is subject to a delay. An exercise of any such function is a significant operational event if it freezes, blocks, burns, or forces the transfer of units held by an AMM Liquidity Pool provided by the TSV, or pauses transfers of an asset held in such a pool, or if the TSV or a Covered Firm supplying liquidity to such a pool holds the function; any other exercise is a significant operational event if it has a significant impact on the operation of the TSV or on its participants.

Recommendation 3 (Notice item (y), added sentence).

> For each asset in a trading pair, state the event on the distributed ledger at which the TSV treats a transfer as final, the legal effect of that event under the terms governing the asset, and the allocation of any loss if a completed transfer is reversed or the asset is frozen after execution.

Recommendation 4 (Section II.G, added minimum fields).

> (vi) the identifier of the transaction on the distributed ledger, and (vii) for any transaction in a pair whose other asset is not denominated in U.S. dollars, the conversion rate used to state the transaction price in U.S. dollars and the source of that rate.

Recommendation 5 (Section IV.A, Notification, added element).

> a description of any key, role, or governance right held by the Covered Firm or any of its affiliates that can set or alter the parameters, fees, code, or pause state of an AMM Liquidity Pool to which the Covered Firm supplies liquidity, and, as of the end of each calendar month, the Covered Firm's share of the liquidity in each such pool.

III. Cross-agency alignment and divergence

Tokenization Systems has commented on adjacent proceedings at eight other agencies. The table below sets out where this Order and its siblings treat the same underlying question differently.

Issue	This Order (File No. 4-927)	Sibling proceedings	Recommended alignment
Equivalence of a tokenized instrument to the asset it represents	Section II.E deems equivalence by four shareholder rights and asks the TSV to describe its verification steps	CFTC Staff Letter 25-39 tells market participants to consider whether a tokenized form of an asset provides a holder with "legal and economic rights that are the same or functionally equivalent to the rights of the asset in traditional form"; it does not find that any token meets that test. Tokenization Systems asked the CFTC (Docket CFTC-2026-1685) to specify the form in which a registrant records that equivalence determination	One evidentiary form, covering custody, controlling record, insolvency posture, and finality, so that a token judged equivalent in one market is judged on the same facts in another
Who can change, freeze, or mint an asset	Notice item (n) reaches the TSV's own contracts only	Treasury's proposed Sec. 1523.3(c) turns on a foreign issuer's technological capability to comply with lawful orders; proposed Regulation Crypto Assets calls for governance and permissions disclosure (91 Fed. Reg. at 54527)	One inventory format for privileged functions, read from the ledger, usable by every agency that relies on it
Nominal versus effective control	Affiliation is the power to direct management or policies	Tokenization Systems has asked FinCEN and the FDIC to look to effective rather than nominal control	Treat control of a pool's or asset's privileged functions as control (Recommendation 6)

Issue	This Order (File No. 4-927)	Sibling proceedings	Recommended alignment
Finality and ledger disruptions	Notice items (y) and (z) ask for clearance and settlement arrangements and for risks, without a legal point of finality (Recommendation 3)	The CFTC's October 2026 advance notice on crypto asset transactions and markets (RIN 3038-AF80) asks whether its core principles should address "forks and other blockchain system reorganizations, or pricing oracle failures" (91 Fed. Reg. at 64834)	Common definitions of finality and of reorganization handling, so that one trade is not final under one Commission's regime and reversible under the other's
A payment stablecoin as the paired asset	Any non-security crypto asset may be paired; footnote 24 declines to interpret whether a TSV is a digital asset service provider	GENIUS Act section 3(b)(1) restricts digital asset service providers' offers and sales of payment stablecoins not issued by a permitted payment stablecoin issuer from July 18, 2028; Treasury's proposal implements it	State, with Treasury and before July 18, 2028, how section 3(b)(1) applies to a TSV pairing (Recommendation 7)

IV. Anticipated objections

Objection: a TSV does not control the token contracts of the assets it lists and cannot answer for them. It does not need to control them. It chooses which assets to list, Section II.E already makes it responsible for verifying a Tokenized NMS Stock's rights, and item (h) already asks it to describe how it evaluates the technical soundness of each Tokenized NMS Stock and of the ledger on which it is issued. The privileged functions of a token deployed on a public ledger can be read from the ledger without the token issuer's cooperation, which is why the Order's own transparency condition makes Recommendation 2 inexpensive. Hedera Hashgraph's comment of October 9, 2026 asks the Commission to allow a TSV's smart contracts "to be deployed on a public, permissioned distributed ledger," and Tokenization Systems takes no position on that request; Recommendation 2 needs only that anyone can read the ledger, which Hedera's description of its own public network keeps: "anyone can read from it or build on top of it."

Objection: these conditions burden a temporary exemption meant to be light. Each recommended item is either a public fact or a fact the TSV must already establish to meet a condition the Order imposes. The cost of not collecting them is borne later: data the Order does not collect during its five-year term cannot be reconstructed when the Commission turns to rulemaking, and the Chairman's statement on the Order describes its purpose as "using that insight to inform a nimbler and future-ready regulatory framework."

Objection: disclosing privileged functions would discourage emergency stops and other protective controls. It would not, and should not. The Order itself cites the President's Working Group recommendation to "consider emergency stops and circuit breakers for unexpected smart contract issues" (91 Fed. Reg. at 60181). Recommendation

2 does not ask a TSV or an issuer to give up such a control. It asks who holds it and whether its use requires more than one person, which is what a TSV Participant needs to know to rely on it.

V. Conclusion

The seven recommendations share one organizing point. The Order is an instrument for learning, and what it can teach depends on what it collects. Whether a token gives its holder the position of a shareholder, who can change or freeze the assets in a pool, when a trade is final, and whether a reported dollar price reflects the stock or the stablecoin are all questions the public ledger can answer, if the Order asks for the answers in a form that can be checked against it. Tokenization Systems supports the Commission's decision to let this market develop under conditions, and offers these recommendations so that the evidence the Order generates will support the rulemaking the Commission anticipates. Tokenization Systems is available to provide the underlying data, methods, and analysis cited in the appendix.

Respectfully submitted,

Zach Zukowski
